ART: Arterial revascularization trial

ATT: average treatment effect on the treated

BITA: Bilateral internal thoracic arteries

CABG: coronary artery bypass grafting

COPD: chronic obstructive pulmonary disease

IPTW: inverse probability of treatment weighting

LVEF: left ventricular ejection fraction

MAG: multiple arterial graft

MI: myocardial infarction

PCI: percutaneous coronary intervention

PVD: peripheral vascular disease

PS: propensity score

RA: radial artery

RCA: right coronary artery

SAG: single arterial graft

SITA: Single internal thoracic artery

SVG: saphenous vein graft

SMD: standardized mean difference

TAG: total arterial graft

1 Abstract

2 Background: The Arterial Revascularization Trial (ART) was designed to compare 10 years survival in
3 bilateral (BITA) vs. single internal thoracic artery (SITA) grafts. The intention to treat analysis has
4 showed comparable outcomes between the two groups but an explanatory analysis suggested that
5 those receiving 2 or more arterial grafts had better survival. Whether the exclusive use of arterial
6 grafts provide further benefit is unclear.

7 Methods: We performed an exploratory analysis of the ART based on conduits actually received (as
8 treated principle). Among 3102 patients enrolled in ART, only those receiving at least 3 grafts were
9 included. Patients receiving single arterial graft (SAG) plus saphenous vein graft (SVG) were included
10 in the SAG group; patients receiving 2 or more arterial grafts with additional SVG were included in
11 the multiple arterial graft (MAG) group; patients receiving arterial grafts only were included in the
12 total arterial graft (TAG) group. Inverse probability of treatment weighting (IPTW) was used for
13 comparison.

14 Results: The final population consisted of 1084, 1010 and 390 patients in the SAG, MAG and TAG
15 group respectively. IPTW analysis showed that when compared to the SAG group, there was a
16 significant trend toward a reduction of 10-year mortality in the MAG and TAG group (test for trend
17 $P=0.02$) and TAG group was associated with the lowest risk of late mortality (HR 0.68; 95% CI 0.48-
18 0.96; $P=0.03$). TAG was also associated with a significant risk reduction of the composite of
19 death/MI/stroke and repeat revascularization (HR 0.71; 95%CI 0.53-0.94; $P=0.02$).

20 Conclusions: When compared to SAG, both MAG and TAG represent valuable strategies to improve
21 clinical outcomes following CABG but TAG can potentially provide further benefit.

22 **Introduction**

23 Graft failure after coronary artery bypass grafting (CABG) causes recurrent angina, need for repeat
24 intervention and poorer survival [1]. Arterial grafts (AG) including bilateral internal thoracic artery
25 (BITA) grafts and/or the radial artery (RA) have been consistently shown to provide superior
26 angiographic patency rates when compared to saphenous vein grafts (SVG) [2-3] and the exclusive
27 use of arterial grafts (total arterial grafting, TAG) has also been advocated as the best
28 revascularization strategy [4-9]. However, TAG is still largely underutilised to supplement a single
29 arterial graft (SAG) and multiple arterial graft (MAG) strategies.

30 The Arterial Revascularization Trial (ART) was designed to compare 10 years survival in bilateral
31 (BITA) vs. single internal thoracic artery (SITA) grafts. The intention to treat analysis has shown
32 comparable outcomes between the two groups [10]. However, SVG was used in 60% of BITA grafts
33 and this may have partially contributed to the equipoise observed in the intention to treat analysis.
34 Hence, we aimed to investigate the potential advantage of TAG versus MAG with additional SVG
35 over SAG strategy by performing an exploratory analysis of the ART based on conduits actually
36 received (as treated)

37 **Material and Methods**

38 This research adheres to the principles set forth in the Declaration of Helsinki
39 (<http://www.wma.net/en/30publications/10policies/b3/index.html>). For the purpose of the
40 present post-hoc analysis, patients from the ART (n=3102) were classified according to an as treated
41 principle depending on number of SVG and arterial grafts actually received. Patients receiving a
42 single arterial graft (SAG) plus saphenous vein graft (SVG) were included in the SAG group; patients
43 receiving 2 or more arterial grafts with additional SVG were included in the multiple arterial graft
44 (MAG) group; patients receiving arterial grafts only included in the total arterial graft (TAG) group.
45 The primary endpoint was 10-year survival. Inverse probability of treatment weighting (IPTW) was

46 used for comparison. In the present analysis we included only those patients who received 3 or
47 more grafts. Patients with no information on whether supplemental conduits were radial artery or
48 vein (n=25), those who received 1 graft only (n=20), those not receiving at least 1 internal thoracic
49 artery (n=35) or those where multiple arterial grafting was achieved exclusively using sequential
50 single internal thoracic artery graft (n=85) were excluded.

51 **Trial design**

52 The ART was approved by the institutional review board of all participating centers, and informed
53 consent was obtained from each participant. The protocol for the ART has been published [11].
54 Briefly, the ART is a 2-arm, randomized multicenter trial conducted in 28 hospitals in 7 countries,
55 with patients being randomized equally to SITA or BITA grafts. Eligible patients were those with
56 multivessel coronary artery disease involving at least the left anterior descending artery and the
57 circumflex artery undergoing CABG including urgent patients. Only emergency patients (refractory
58 myocardial ischemia/cardiogenic shock) and those requiring single grafts or redo CABG were
59 excluded.

60 **Follow-up**

61 Questionnaires were sent to study participants by mail every year after surgery. No clinic visits were
62 planned apart from the routine clinical 6-week post-operative visit. Participants were sent stamped
63 addressed envelopes to improve the return rates of postal questionnaires. Study coordinators
64 contacted participants by telephone to alert them to the questionnaire's arrival and to ask them
65 about medications, adverse events and health services resource use.

66 **Study outcomes**

67 For the present analysis the primary outcome was 10-year mortality and the composite of death,
68 myocardial infarction, stroke and/or repeat revascularization.

69 **Definitions**

ART definitions were used for the present analysis. The burden of native coronary artery disease was assessed by reporting the following four characteristics for each graft performed: quality of the target (1 to 3, 1=good, 2 moderate, 3=poor), vessel diameter assessed by means of intraoperative probes and the need for endarterectomy.

Death was classified into cardiovascular and non-cardiovascular causes, where possible, using autopsy reports and death certificates. Congestive heart failure, arrhythmia or myocardial infarction, pulmonary embolus and dissection were considered cardiovascular causes of death. Because pulmonary embolus and dissection are not directly related to the conduits used, in the present analysis we considered all-cause death only. MI was diagnosed when two of the following three criteria were present: 1. Unequivocal ECG changes; 2. Elevation of cardiac enzyme(s) above twice the upper limit of normal or diagnostic troponin rises; 3. Chest pain typical for acute MI which lasted more than 20 minutes. Stroke was defined as new neurological deficit evidenced by clinical signs of paresis, paraplegia or new cognitive dysfunction including any mental status alteration lasting more than 24 hours and/or evidence on CT or MRI scan of recent brain infarct (less than 6 months). Repeat revascularization was defined as coronary bypass surgery or percutaneous coronary intervention (PCI) performed after the initial trial procedure.

Statistical analysis

Continuous variables were reported as mean and standard deviation and categorical variables were reported as count and percentage. The rate of missing data was less than 1% for all variables included in the propensity score model. The mean and the most frequent value were used to impute continuous and categorical variables, respectively. To compare the three groups, inverse probability of treatment weighting (IPTW) was used and the treatment effect on the treated (ATT) was estimated to draw inferences about the relative effectiveness of the three treatment groups. For this purpose, a generalized boosted model was implemented to estimate propensity scores (PS)

adjusting for pre-treatment covariates, age, female sex, diabetes, chronic obstructive pulmonary disease (COPD), asthma, creatinine, left ventricular ejection fraction (LVEF), peripheral vascular disease (PVD), pre-operative atrial fibrillation (AF), myocardial infarction (MI), right coronary artery (RCA) disease, off-pump status, race, NYHA functional class, hypertension, hyperlipaemia, cerebrovascular disease. The propensity score was assumed as the probability that an individual with pre-treatment characteristics X receives SAG (twang R package). We gave each treatment case a weight of 1 and each comparison case a weight $w_i = p(x_i)/(1 - p(x_i))$. The absolute standardised mean difference (SMD) was used as a balance metric to summarize the difference between two univariate distributions of a single pre-treatment variable. A value ≥ 0.10 was considered as an indicator of imbalance. The treatment effect estimates on primary endpoints were obtained by using a doubly robust estimation which combines a form of outcome regression (multivariate proportional hazard model) with a model for the exposure (i.e., IPTW). SAG was used as reference in all comparisons. A combination of IPTW and covariate adjustment corrects for residual imbalance after weighting. Moreover, treatment effect estimators that utilize an outcomes regression model and propensity scores are “doubly robust” in the sense that if either the propensity score model is correct or the regression model is correct then the treatment effect estimator will be unbiased. Treatment effect was reported as hazard ratio (HR) and 95% confidence interval (95%CI). Sub-distribution HR were calculated for non-fatal endpoints (MI, stroke, repeat revascularization). Doubly robust adjustment was also used for test for trend analysis to investigate whether the hypothesis of an incremental benefit from MAG over SAG and from TAG over SAG. Surgeon ID was included as a stratifying variable to account for surgeon related clustering effect. Treatment effect was also estimated after restricting analysis to patients older than 70 years and with insulin-dependent diabetes. For sensitivity analysis we pooled TAG and MAG strategies in a single group (MAG/TAG group) and compared with a SAG using multivariable Cox regression model. For

completeness, unadjusted comparisons were estimated forcing the treatment variable only in the regression model.

For each patient, we also calculated the TAG index according to the following formula:

$$TAG\ index = \frac{Number\ of\ Arterial\ Grafts}{Number\ of\ Total\ Grafts}$$

The TAG index is an intuitive index of the proportion of revascularization achieved with arterial grafts. TAG index =1 correspond to arterial grafts only (TAG) while TAG index =0 corresponds to revascularization with SVG only. By forcing the TAG index (as a continuous and categorial variable as $< \frac{1}{3}; \frac{1}{3} to \frac{2}{3}; > \frac{2}{3}$) into a multivariable Cox model stratified by number of total grafts, we tested the hypothesis of a significant relationship between the proportion of arterial revascularization and a reduction of 10 year-adverse events. The relationship between different values of TAG index and risk of adverse events was reported as hazard ratio (HR) and 95% confidence interval (95%CI) using the median value of TAG index as reference.

All p-values <0.05 were considered as indicating statistical significance. As sensitivity analysis, treatment effect was tested in a multivariable Cox regression analysis stratified by number of grafts. All statistical analysis was performed using R Statistical Software (version 3.2.3; R Foundation for Statistical Computing, Vienna, Austria).

Results

The final population consisted of 1084, 1010 and 390 patients in the SAG, MAG and TAG group respectively. Only 139 (5.6%) patients did not complete the 10-year follow up, 59 (5.4%) in the SAG, 56 (5.5%) in the MAG and 24 (6.1) in the TAG group. The mean follow-up in this group was 5.2 years. The graft configuration used in each group is summarised in Supplementary Table 1. The three groups presented some differences in baseline characteristics (Table 1, average SMD>0.10). In particular, patients in the TAG group were 2 years younger on average and were less likely to have

142 a concomitant RCA disease, a worse NYHA functional class but more likely to have an LVEF <50%.
143 Guideline directed medical therapy at 10 years is shown in Supplementary Table 4. PS weighting
144 created 3 groups comparable for all baseline characteristics (Table 2, Figure 1, Supplementary Table
145 2 and Supplementary Figure 2). The distinction between cardiovascular and non-cardiovascular
146 cause of death is presented in Supplementary Table 5, and supplementary Table 6 shows the
147 incidence of sternal wound infection requiring reconstruction.

148 10 year-outcome analysis is reported in Table 3. In the PS-weighted sample, we observed a
149 significant trend toward a reduction of 10-year mortality across the three groups (test for trend
150 =0.02; Figure 2A) and TAG was associated with a significant risk reduction of all-cause death when
151 compared to SAG (HR 0.68; 95% CI 0.48-0.96;P=0.03). The same trend was observed for the
152 revascularization (P=0.04) and the composite of death/MI/stroke and repeat revascularization
153 (P=0.01) with TAG being associated with a significant risk reduction of the composite of
154 death/MI/stroke and repeat revascularization (0.71; 95%CI 0.53-0.94; P=0.02; Figure 2B) when
155 compared to SAG.

156 The results of analysis in patients older than 70 years old and insulin-dependent diabetic patients
157 are depicted in supplementary Tables 7, 8. TAG was associated with a lower incidence of mortality,
158 and both MAG and TAG with lower incidence of the composite of mortality, MI, stroke and/or
159 revascularization in insulin-dependent diabetic patients. Multivariable Cox models (Supplementary
160 Table 3) confirmed that when compared to SAG, TAG was associated with a significant risk reduction
161 of 10-year mortality and that MAG and TAG were associated with a significant risk reduction of the
162 composite of death, MI, stroke and repeat revascularization.

163 When TAG and MAG strategies were pooled together in a single group (MAG/TAG group), they were
164 superior to SAG in terms of 10-year mortality and incidence of MACCE (Supplementary Table
165 9). Supplementary Table 10 depicts the unadjusted treatment effect estimation.

166 Finally, we observed a significant linear relationship between the TAG index and the risk of 10-year
167 mortality (HR 0.68; 95% CI 0.47-0.97; P=0.03) and composite outcome (HR 0.68; 95%CI 0.51-
168 0.90;P=0.007, Figure 3A and Figure 3B; Table 4). When the TAG index was used as categorical
169 variable, when compared to cases with TAG index $< \frac{1}{3}$, a larger proportion of arterial
170 revascularization (TAG index between $\frac{1}{3}$ and $\frac{2}{3}$ or TAG index $> \frac{2}{3}$) was associated with a
171 significantly lower risk of 10-year mortality and composite of death/MI/stroke and repeat
172 revascularization.

173 Discussion

174 The main finding of the present post-hoc analysis of the ART was that we observed an incremental
175 benefit in moving from SAG to MAG and TAG in terms of reduction of 10-year mortality and the
176 composite of death/MI/stroke and repeat revascularization. When compared to SAG, MAG group
177 showed a numerically lower rate of 10-year mortality and the composite of death, MI, stroke and
178 revascularization. In the TAG group, this difference became statistically significant.

179 For each patient, we calculated the TAG index which is an intuitive index of the proportion of
180 revascularization achieved with arterial grafts. We found that there was a liner relationship between
181 the TAG index and the risk reduction in 10-year mortality and composite endpoint.

182 Despite recent advances in secondary prevention following CABG, including statin therapy and
183 dual antiplatelet therapy [12], long-term SVG patency rates still remain inferior to those of arterial
184 grafts [2-3]. SVG failure can occur in up to 40% of patients and it is associated with a significantly
185 increased risk of the composite of adverse events [13]. However, SVG is still widely used during
186 CABG not only to supplement the SITA graft but also when additional arterial grafts are used [14].
187 The exclusive use of arterial grafts is perceived as technically more demanding [15] and remains
188 largely underutilized [14]. This is partially due to the limited evidence supporting the superiority of
189 TAG over other revascularization strategies using SVG. A recent meta-analysis of four small

190 randomized controlled trials [16] with short term follow-up, plus 21 observational studies found
191 that when compared to no-TAG, TAG was associated with reduced long-term all-cause mortality in
192 observational studies matched/adjusted for confounders (incident rate ratio 0.85, 95% CI: 0.81–
193 0.89, $p = 0.0001$; $I^2 = 0\%$) and unmatched/unadjusted (incident rate ratio 0.67, 95% CI: 0.59–0.76,
194 $p = 0.0001$; $I^2 = 67\%$). Decreases in major cardiovascular outcomes and revascularization did not
195 achieve statistical significance. Moreover, when compared to patients with two arterial grafts, TAG
196 was still associated with reduced long-term all-cause mortality (incident rate ratio 0.85, 95% CI:
197 0.73–0.99, $p=0.04$) with minimal heterogeneity ($I^2=5\%$).

198 The ART trial was designed to compare 10-year survival after BITA vs SITA grafts. No significant
199 differences were found at 10 years between the 2 groups according to the intention to treat
200 analysis [10]. However, the relatively high rate of cross-over (14%) may have influenced these
201 results and an exploratory analysis supported the hypothesis that patients receiving 2 or more
202 arterial grafts was associated with a lower risk of mortality. However, a large proportion of
203 patients receiving additional arterial grafts were also treated with SVG to complete surgical
204 revascularization and what remains unclear it is whether the exclusive use of arterial grafts was
205 associated with a further benefit.

206 The present post-hoc analysis of the ART trial showed that both MAG with additional SVG and TAG
207 were associated with a numerically lower incidence of adverse events (mortality and composite of
208 mortality, MI, stroke and/or revascularization) but TAG was associated with a larger and statistically
209 significant advantage. In particular, TAG was associated with a significant reduction of 10-year
210 mortality and rate of repeat revascularization. When analysis was restricted to high risk subgroups,
211 TAG and MAG strategies were beneficial in patients with insulin-dependent diabetes but not in
212 patients older than 70 years. These results are supported by a recent study from New York State
213 [17] which reporting that MAG was beneficial only in patients younger than 70 years old but not in

214 diabetic patients. However this analysis did not discriminate between insulin-dependent and orally
215 treated subjects.

216 We also found an inverse association between the risk of 10-year adverse events and the proportion
217 of revascularization achieved with arterial grafts (TAG index).

218 Although the present comparison is observational in nature, propensity score weighed groups were
219 comparable for all relevant characteristics. Moreover, it should be noted that patients enrolled in a
220 trial are more homogeneous than those from observational cohorts.

221 Despite this, however, the main limitation of the present analyses is that it remains a non
222 randomized comparison. While propensity score modelling included all baseline variables, we
223 cannot exclude a residual selection bias based on unmeasured or unmeasurable characteristics.

224 Moreover, assessment of extension and severity of native coronary disease was based on
225 qualitative surgeon assessment and not on the SYNTAX score.

226 In the ART when patients were randomized between 2004-2007 the only formal exclusion criteria
227 were patients requiring a single graft, redo patients or those with evidence of an evolving
228 myocardial infarction. However the ART population may now, by current standards, be
229 considered low risk for CABG and their generalizability to a contemporary cohort of patients, who
230 are more likely to be older and sicker, remains to be determined.

231 Additionally, the impact of surgeon expertise in ART has been addressed in a previous paper using
232 the BITA conversion of BITA to SITA rate as a proxy of surgical expertise [18]. This approach could
233 not be replicated in the present study due to the lack of information regarding the use of radial
234 artery. However, to account for the potential influence of individual surgeon experience, our
235 modelling of outcomes was stratified according to the surgeon performing the operation and
236 results showed a favourable effect of TAG on 10-year incidence of death and of both MAG and
237 TAG on the composite of death, stroke, myocardial infarction and revascularization.

238 In conclusion, the present post-hoc ART analysis showed that in ART there was an increasing
239 benefit on 10-year outcomes by increasing the extension of arterial revascularization. As a
240 consequence, MAG and TAG were associated with lower incidence of adverse events but TAG was
241 associated with the greatest benefit. These findings support the hypothesis that both MAG and
242 TAG represent valuable strategies in order to improve clinical outcomes following CABG but TAG
243 can potentially provide further benefit in an appropriately selected population. Further studies
244 including the ongoing ROMA trial [19], are necessary to provide final evidence into the potential
245 benefit of total arterial revascularization.

324 **Figure legends**

325 Figure 1. The Love plot shows the changes in standardized mean difference before and after
326 matching. It demonstrates that the balance of covariates was improved on all variables, which are
327 below the threshold of 0.1 of absolute mean difference.

328 Figure 2A. Kaplan-Meier curves showing cumulative 10-year mortality in the three groups after
329 inverse probability of treatment weighting (IPTW). The confidence limit of each curve is shown as
330 shaded area. SAG single arterial graft, MAG multiple arterial graft, TAG total arterial graft.

331 Figure 2B. Kaplan-Meier curves show cumulative 10-year incidence of composite of death, MI,
332 stroke and repeat revascularization in the three groups after inverse probability of treatment
333 weighting (IPTW). The confidence limit of each curve is shown as shaded area. SAG single arterial
334 graft, MAG multiple arterial graft, TAG total arterial graft.

335 Figure 3A. Linear relationship between the TAG index and the risk of 10-year mortality. TAG index
336 median (0.5) as reference.

337 Figure 3B. Kaplan-Meier curve show cumulative 10-year mortality according to the TAG index. The
338 confidence limit of each curve is shown as shaded area.

339 Supplementary Figure 1. Standardized mean difference before and after inverse probability of
340 treatment weighting for each comparison (1: single arterial graft (SAG), 2: multiple arterial graft
341 (MAG); 3: total arterial graft (TAG)).

SAG single arterial graft, MAG multiple arterial graft, TAG total arterial graft. MI, myocardial infarction

- 1 Supplementary Table 10. Treatment effect estimation in the overall population without
- 2 adjustment.

		10-y cumulative incidence	HazardRatio	CI.95	p-value
All-cause death (P-trend=0.003)					
	SAG	24.6%	Ref		
	MAG	20.2%	0.80	[0.67;0.97]	0.02
	TAG	17.9%	0.71	[0.54;0.93]	0.01
MI (P-trend=0.33)					
	SAG	5.5%	Ref		
	MAG	5.0%	0.88	[0.60;1.30]	0.53
	TAG	4.6%	0.77	[0.44;1.35]	0.37
Revascularization (P=0.35)					
	SAG	11.3%	Ref		
	MAG	11.1%	0.95	[0.72;1.24]	0.70
	TAG	9.9%	0.83	[0.56;1.21]	0.33
STROKE (P-trend=0.09)					
	SAG	5.6%	Ref		
	MAG	4.3%	0.76	[0.51;1.15]	0.20
	TAG	3.7%	0.64	[0.35;1.18]	0.15
Death/MI/STROKE/revascularization (P-trend=0.001)					
	SAG	37.0%	Ref		
	MAG	31.1%	0.80	[0.68;0.92]	0.003
	TAG	30.2%	0.76	[0.62;0.94]	0.01

- 3 *SAG single arterial graft, MAG multiple arterial graft, TAG total arterial graft. MI, myocardial infarction.*

4

1 Figure 1. The Love plot shows the changes in standardized mean difference before and after
 2 matching. It demonstrates that the balance of covariates was improved on all variables,
 3 which are below the threshold of 0.1 of absolute mean difference.

4

5

1 Figure 2A. Kaplan-Meier curves showing cumulative 10-year mortality in the three groups
 2 after inverse probability of treatment weighting (IPTW). The confidence limit of each curve
 3 is shown as shaded area. SAG single arterial graft, MAG multiple arterial graft, TAG total
 4 arterial graft.

5

6

1 Figure 2B. Kaplan-Meier curves show cumulative 10-year incidence of composite of death,
 2 MI, stroke and repeat revascularization in the three groups after inverse probability of
 3 treatment weighting (IPTW). The confidence limit of each curve is shown as shaded area.
 4 SAG single arterial graft, MAG multiple arterial graft, TAG total arterial graft.

5

- 1 Figure 3A. Linear relationship between the TAG index and the risk of 10-year mortality. TAG
- 2 index median (0.5) as reference.

3

4

- 1 Figure 3B. Kaplan-Meier curve show cumulative 10-year mortality according to the TAG
- 2 index. The confidence limit of each curve is shown as shaded area.

3

4

Supplementary Figure 1. Standardized mean difference before and after inverse probability of treatment weighting for each comparison (1: single arterial graft (SAG), 2: multiple arterial graft (MAG); 3: total arterial graft (TAG)).
